

What is RPC

RPC stands for `remote procedure call`. As the name suggests, it lets you call a function in on a different process/server/backend and get back a response from it.

Why remote procedure call?

This is how we've made our backends talk to each other until now.

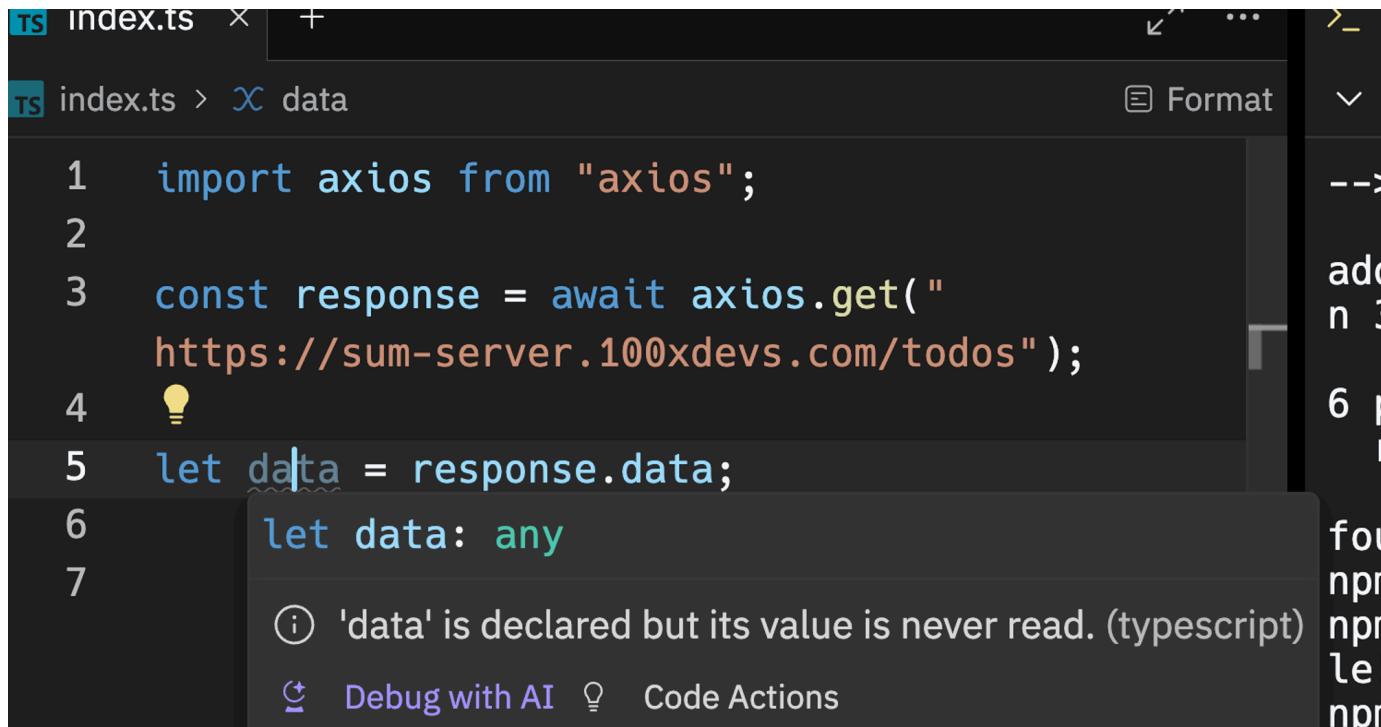

We send out an `http request`, get back a response.

There are a few flaws in this approach

1. No types. You don't know what is the shape of the data you will get back. You might be able to share types between 2 Node.js backends somehow, but if the other backend is in `Rust`, then you can't get back the types from it
2. We use JSON to `serialize` and `deserialize` data
3. We have to know what `axios` is, or what `fetch` is. We need to understand HTTP and how to call it
4. Not language agnostic at all. We have to use a different library in Java, Go, Rust to send an `http` request to the server

Let's try doing a quick HTTP request to <https://sum-server.100xdevs.com/todos> from a Node.js server

```
1 import axios from "axios";
2
3 const response = await axios.get(
4   "https://sum-server.100xdevs.com/todos");
5
6 let data = response.data;
7 let data: any
```

ⓘ 'data' is declared but its value is never read. (typescript)

⚡ Debug with AI ☰ Code Actions

Implementing a dump RPC

What if we could `auto generate` a `client` that a Node.js server can use and `call` a function on another service without worrying about the underlying `axios` / `fetch` call

rpc.ts (autogenerated)

```
import axios from "axios";
interface Todo {
  id: string;
  title: string;
  description: string;
  completed: boolean;
}

async function getTodos(): Promise<Todo[]> {
  const response = await axios.get(" https://sum-server.100xdevs.com/tod
let todos = response.data.todos;
```

Copy

```
    return todos;
}
```

index.ts

```
import { getTodos } from "./rpc"
const todos = await getTodos();
console.log(todos);
```

Benefits

1. Better types - The `getTodos` function has an associated type of the data being returned.
2. We are still using json, but we will fix that soon (json is slow)
3. We don't need to use axios anymore, all we have to do is call a function
4. If we can get `autogenerated` code for all languages (go, rust), then this becomes language agnostic

Sample clients in other languages

Rust

```
use reqwest::Error; // Add reqwest = { version = "0.11", features = ["json"] }

#[derive(Debug)]
struct Todo {
    id: String,
    title: String,
    description: String,
    completed: bool,
}

async fn get.todos() -> Result<Vec<Todo>, Error> {
    let response = reqwest::get("https://sum-server.100xdevs.com/todos")

    let todos: Vec<Todo> = response.json().await?;
    Ok(todos)
}
```

Go

[Copy](#)

```
import (
    "encoding/json"
    "fmt"
    "io/ioutil"
    "net/http"
)

type Todo struct {
    ID      string `json:"id"`
    Title   string `json:"title"`
    Description string `json:"description"`
    Completed bool   `json:"completed"`
}

func getTodos() ([]Todo, error) {
    response, err := http.Get("https://sum-server.100xdevs.com/todos")
    if err != nil {
        return nil, err
    }
    defer response.Body.Close()

    body, err := ioutil.ReadAll(response.Body)
    if err != nil {
        return nil, err
    }

    var todos struct {
        Todos []Todo `json:"todos"`
    }
    if err := json.Unmarshal(body, &todos); err != nil {
        return nil, err
    }

    return todos.Todos, nil
}
```

Proto buffs

Ref <https://protobuf.dev/>

Protocol buffers are Google's language-neutral, platform-neutral, extensible mechanism for serializing structured data – think XML, JSON.

The protocol buffers are where we define our service definitions and messages. This will be like a contract or common interface between the client and server on what to expect from each other; the methods, types, and returns of what each operation would bear.

1. **Schema Definition Language:** Protocol Buffers use a schema definition language (`.proto` files) to define the structure of data. This language allows you to specify message types, fields, enums, and services.
2. **Binary Serialization:** Protocol Buffers serialize data into a binary format, which is more compact and efficient compared to text-based formats like XML and JSON.
3. **Language Support and Code Generation:** Protocol Buffers support code generation for a wide range of programming languages, including C++, Java, Go, Python, JavaScript, Ruby, and more. Protocol Buffers come with tools (e.g., `protoc`) that generate code in various programming languages based on your `.proto` files.

Let's create a simple Proto file

message.proto

```
syntax = "proto3";  
  
// Define a message type representing a person.  
message Person {  
    string name = 1;  
    int32 age = 2;  
}  
  
service PersonService {  
    // Add a person to the address book.  
    rpc AddPerson(Person) returns (Person);  
  
    // Get a person from their name  
    rpc GetPersonByName(GetPersonByNameRequest) returns (Person);  
}  
  
message GetPersonByNameRequest {
```

Copy

```
    string name = 1;  
}
```

There are a few things to unpack here -

- **message** - A message that can be encoded/decoded/transferred
- types
 - string
 - int32
- service - Describes what all **rpc** methods you support
- **Field numbers**

In Protocol Buffers, each field within a message type is assigned a unique numerical identifier called a tag or field number. These field numbers serve several purposes:

1. **Efficient Encoding:** Field numbers are used during serialization and deserialization to efficiently encode and decode the data. Instead of including field names in the serialized data, Protocol Buffers use field numbers, which are typically more compact and faster to process.
2. **Backward Compatibility:** Field numbers are stable identifiers that remain consistent even if you add, remove, or reorder fields within a message type. This means that old serialized data can still be decoded correctly by newer versions of your software, even if the message type has changed.
3. **Language Independence:** Field numbers provide a language-independent way to refer to fields within a message type. Regardless of the programming language used to generate the code, the field numbers remain the same, ensuring interoperability between different implementations.

Serializing and deserializing data (easy)

<https://www.protobufpal.com/>

The screenshot shows the Protobufpal interface. On the left, there's a code editor titled "Protobuf Definition - Proto" containing a .proto file. The file defines a Person message with fields name (string) and age (int32), and an AddressBookService with methods AddPerson and GetPersonByName. On the right, there's a "Decoded Message - JSON" viewer showing a JSON object with "name": "harkirat" and "age": 21. Below the code editor, there's a section for "Encoded Message" with options for Base64 and Hex, showing the encoded bytes: CghoYXJraXJhdBAV.

[About](#)[Examples](#)

Serializing and deserializing data (hard)

- Create a.proto
- npm init -y
- npm i protobufjs

```
const protobuf = require('protobufjs');

// Load the Protocol Buffers schema
protobuf.load('a.proto')
  .then(root => {
    // Obtain the Person message type
    const Person = root.lookupType('Person');

    // Create a new Person instance
    const person = { name: "Alice", age: 30 };

    // Serialize Person to a buffer
    const buffer = Person.encode(person).finish();

    // Write buffer to a file
    require('fs').writeFileSync('person.bin', buffer);

    console.log('Person serialized and saved to person.bin');

    // Read the buffer from file
  })
  .catch(error => {
    console.error(`Error loading schema: ${error}`);
  });
}

// Load the schema and get the Person message type
const Person = protobuf.load('a.proto').lookupType('Person');

// Create a new Person instance
const person = { name: "Alice", age: 30 };

// Serialize Person to a buffer
const buffer = Person.encode(person).finish();

// Write buffer to a file
require('fs').writeFileSync('person.bin', buffer);

console.log('Person serialized and saved to person.bin');

// Read the buffer from file

```

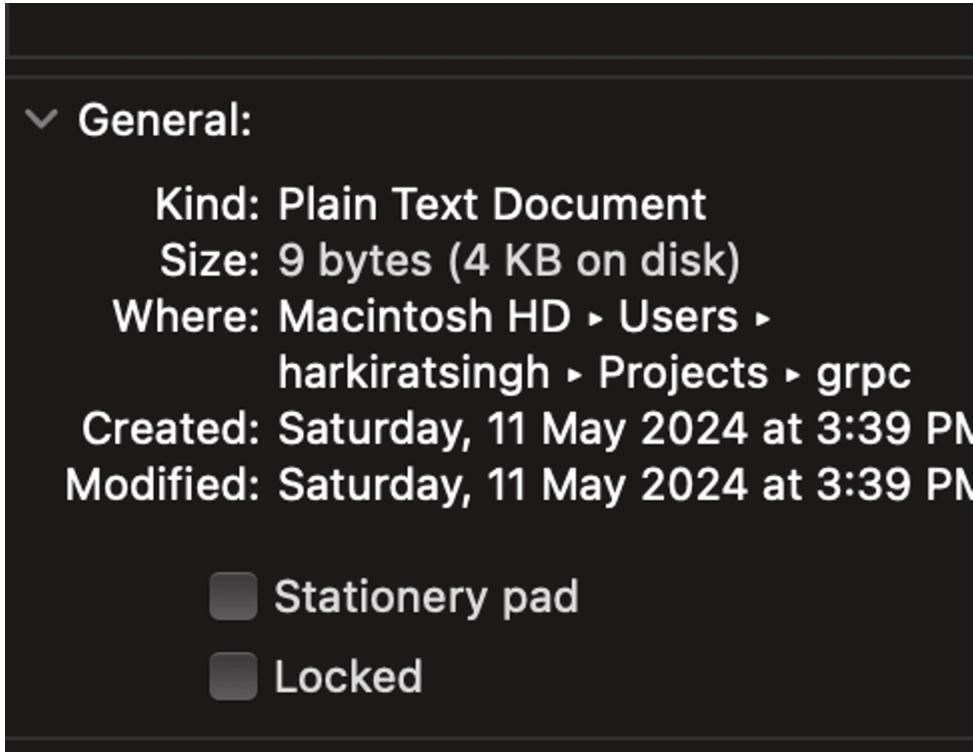

[Copy](#)

```
const data = require('fs').readFileSync('person.bin');

// Deserialize buffer back to a Person object
const serializedPerson = Person.decode(data);

console.log('Person serialized from person.bin:', serializedPerson)
.catch(console.error);
```

- Check the size of person.bin

- Create a `person.json` file and check it's size

```
{  
  name: "Alice",  
  age: 31  
}
```

Some common RPC protocols

JSON RPC

Used by solana/eth when talking to the blockchain.

The screenshot shows a Postman request to https://solana-mainnet.g.alchemy.com/v2/qNRDJCmqFGo_0gxkBNVXx745lvY1k6kM. The request method is POST. The body contains a JSON object:

```

1 {
2   "jsonrpc": "2.0",
3   "id": 1,
4   "method": "getBalance", → function to call
5   "params": [→ arguments
6     "5zxNfsvbeG95wkm4jLHzBfnvfVQMW7LvWLpj5xrEKkn"
7   ]
8 }
9

```

The response status is 200 OK, with a response body:

```

1 {
2   "jsonrpc": "2.0",
3   "result": {
4     "context": {
5       "apiVersion": "1.17.28",
6       "slot": 265100222
7     },
8     "value": 110450670 → solana balance of that account
9   },
10  "id": 1
11 }

```

Creating a JSON RPC Server

```

const express = require('express');
const bodyParser = require('body-parser');

const app = express();
const port = 3000;

// Parse JSON bodies

```

Copy

```
app.use(bodyParser.json());

// Define a sample method
function add(a, b) {
    return a + b;
}

// Handle JSON-RPC requests
app.post('/rpc', (req, res) => {
    const { jsonrpc, method, params, id } = req.body;

    if (jsonrpc !== '2.0' || !method || !Array.isArray(params)) {
        res.status(400).json({ jsonrpc: '2.0', error: { code: -32600, me
            return;
        }

        // Execute the method
        let result;
        switch (method) {
            case 'add':
                result = add(params[0], params[1]);
                break;
            default:
                res.status(404).json({ jsonrpc: '2.0', error: { code: -32601
                    return;
                }

                // Send back the response
                res.json({ jsonrpc: '2.0', result, id });
        });
    }

    // Start the server
    app.listen(port, () => {
        console.log(`JSON-RPC server listening at http://localhost:${port}`)
    });
});
```

Try hitting the server with the following body

```
{  
    "jsonrpc": "2.0",  
    "id": 1,  
    "method": "add",  
    "params": [  
        1, 2  
    ]  
}
```

Copy

GRPC

GRPC is an open-source remote procedure call (RPC) framework developed by Google. It allows you to define services and messages using Protocol Buffers, a language-agnostic data serialization format, and then generate client and server code in various programming languages

TRPC

tRPC gives u types on the frontend and backend if u have a full stack app in js.

We have a video from cohort 1 on it. Not used too much

Types in pb

Protobuffs give you access to a lot of types/enums/message types

1. Scalar Types:

- **int32, int64, uint32, uint64**: Signed and unsigned integers of various sizes.
- **float, double**: Floating-point numbers.
- **bool**: Boolean values (true or false).
- **string**: Unicode text strings.
- **bytes**: Arbitrary binary data.

```
syntax = "proto3";

// Define a message type representing an address.
message Address {
    string street = 1;
    string city = 2;
    string state = 3;
    string zip = 4;
}

// Define a message type representing a person.
message Person {
    string name = 1;
    int32 age = 2;
    Address address = 3;
}
```

[Copy](#)

2. Message Types:

- Message types allow you to define structured data with nested fields. They can contain scalar types, other message types, or repeated fields (arrays).
- You define message types using the **message** keyword followed by the name of the message type and its fields.

```
message Person {
    string name = 1;
    int32 age = 2;
```

[Copy](#)

```
repeated string phone_numbers = 3;
}
```

1. Enum Types:

- Enum types define a set of named constant values.
- You define enum types using the **enum** keyword followed by the name of the enum type and its values.

```
enum PhoneType {
    MOBILE = 0;
    HOME = 1;
    WORK = 2;
}
```

1. Maps

```
message MapMessage {
    map<string, int32> id_to_age = 1;
}
```

Trying a more complicated proto

```
syntax = "proto3";

// Define an enum representing the type of phone numbers.
enum PhoneType {
    MOBILE = 0;
    HOME = 1;
    WORK = 2;
}

// Define a message type representing a phone number.
message PhoneNumber {
    string number = 1;
    PhoneType type = 2;
}

// Define a message type representing an address.
message Address {
```

```
string street = 1;
string city = 2;
string state = 3;
string zip = 4;
}

// Define a message type representing a person.
message Person {
    string name = 1;
    int32 age = 2;
    repeated PhoneNumber phone_numbers = 3;
    Address address = 4;
}
```

Try using it in

Implementing services

This is what our proto file looks like

```
syntax = "proto3";

// Define a message type representing a person.
message Person {
    string name = 1;
    int32 age = 2;
}

service AddressBookService {
    // Add a person to the address book.
    rpc AddPerson(Person) returns (Person);

    // Get a person from their name
    rpc GetPersonByName(string) returns (Person);
}
```

Copy

There is a `service` section which describes all the services our server would support. But `protobufs` are not used for service creation.

While the concept of a service exists in Protocol Buffers, it's up to the developer to choose how to implement the RPC communication. gRPC is one such RPC framework that uses Protocol Buffers for defining services and messages, but other frameworks or custom implementations can also be used.

Implementing services using grpc

Ref - <https://grpc.io/docs/languages/node/basics/>

- Initialize node.js project

```
npm init
```

[Copy](#)

- Initialize typescript

```
npx tsc --init
```

[Copy](#)

- Add dependencies

```
npm i @grpc/grpc-js @grpc/proto-lou...
```

[Copy](#)

- Create a.proto file

```
syntax = "proto3";  
  
// Define a message type representing a person.  
message Person {  
    string name = 1;  
    int32 age = 2;  
}  
  
service AddressBookService {  
    // Add a person to the address book.  
    rpc AddPerson(Person) returns (Person);  
  
    // Get a person from their name  
    rpc GetPersonByName(GetPersonByNameRequest) returns (Person);  
}  
  
message GetPersonByNameRequest {  
    string name = 1;  
}
```

Copy

- Create index.ts

```
import path from 'path';  
import * as grpc from '@grpc/grpc-js';  
import { GrpcObject, ServiceClientConstructor } from "@grpc/grpc-js"  
import * as protoLoader from '@grpc/proto-loader';  
  
const packageDefinition = protoLoader.loadSync(path.join(__dirname, './a  
const personProto = grpc.loadPackageDefinition(packageDefinition);  
  
const PERSONS = [  
    {  
        name: "harkirat",  
        age: 45  
    },  
    {  
        name: "raman",  
        age: 45  
    },  
];  
  
//@ts-ignore  
function addPerson(call, callback) {
```

Copy

```
console.log(call)
let person = {
  name: call.request.name,
  age: call.request.age
}
PERSONS.push(person);
callback(null, person)
}

const server = new grpc.Server();

server.addService((personProto.AddressBookService as ServiceClientConstr
server.bindAsync('0.0.0.0:50051', grpc.ServerCredentials.createInsecure(
  server.start();
});
```

- Run it

```
tsc -b      Copy
node index.js
```

- Test it in postman
 - File ⇒ New ⇒ GRPC
 - Import the proto file in GRPC
 - Send a request (select URL as grpc://localhost:50051)

The screenshot shows the DailyCode interface with a dark theme. At the top, there are tabs for various HTTP methods (GET, POST, etc.) and a tab for 'Untitled'. Below the tabs, the title 'Untitled Request' is displayed. The URL 'grpc://localhost:50051' is entered in the address bar, and the endpoint 'AddressBookService / AddPerson' is selected. A large blue 'Invoke' button is visible on the right. The main area is divided into two sections: 'Message' and 'Response'. In the 'Message' section, line numbers 1 through 4 are shown, with line 3 containing the JSON message: { "name": "harkirat", "age": 20 }. In the 'Response' section, line numbers 1 through 4 are shown, with line 3 containing the same JSON message, indicating a successful response. The status code is listed as '0 OK' with a time of '34 ms'.

Adding types

Ref <https://github.com/grpc/proposal/blob/master/L70-node-proto-loader-type-generator.md>

Ref <https://www.npmjs.com/package/@grpc/proto-loader>

Example Usage

Generate the types:

```
$(npm bin)/proto-loader-gen-types --longs=String --enums=String --defaults
```

Consume the types:

```
import * as grpc from '@grpc/grpc-js';
import * as protoLoader from '@grpc/proto-loader';
import type { ProtoGrpcType } from './proto/example.ts';
import type { ExampleHandlers } from './proto/example_package/Example.ts';

const exampleServer: ExampleHandlers = {
  // server handlers implementation...
};

const packageDefinition = protoLoader.loadSync('./proto/example.proto');
const proto = (grpc.loadPackageDefinition(
  packageDefinition
) as unknown) as ProtoGrpcType;

const server = new grpc.Server();
server.addService(proto.example_package.Example.service, exampleServer);
```

Generate types

```
./node_modules/@grpc/proto-loader/build/bin/proto-loader-gen-types.js
```

Copy

Update the code

```
import path from 'path';
import * as grpc from '@grpc/grpc-js';
import { GrpcObject, ServiceClientConstructor } from "@grpc/grpc-js"
import * as protoLoader from '@grpc/proto-loader';
import { ProtoGrpcType } from './proto/a';
import { AddressBookServiceHandlers } from './proto/AddressBookService';
import { Status } from '@grpc/grpc-js/build/src/constants';
```

Copy

```
const packageDefinition = protoLoader.loadSync(path.join(__dirname, './a  
const personProto = (grpc.loadPackageDefinition(packageDefinition) as un  
  
const PERSONS = [  
  {  
    name: "harkirat",  
    age: 45  
  },  
  {  
    name: "raman",  
    age: 45  
  },  
];  
  
const handler: AddressBookServiceHandlers = {  
  AddPerson: (call, callback) => {  
    let person = {  
      name: call.request.name,  
      age: call.request.age  
    }  
    PERSONS.push(person);  
    callback(null, person)  
  },  
  GetPersonByName: (call, callback) => {  
    let person = PERSONS.find(x => x.name === call.request.name);  
    if (person) {  
      callback(null, person)  
    } else {  
      callback({  
        code: Status.NOT_FOUND,  
        details: "not found"  
      }, null);  
    }  
  }  
}  
  
const server = new grpc.Server();  
  
server.addService((personProto.AddressBookService).service, handler);  
server.bindAsync('0.0.0.0:50051', grpc.ServerCredentials.createInsecure()  
  server.start();  
});
```
